OOP Lab # 2.1

C++ Operators

Instructor: Muhammad Abdullah Orakzai

DEPARTMENT OF COMPUTER SCIENCE

Contents

- 1) Operators in C++
- 2) Unary operators
- 3) Binary operators
- 4) Ternary operators
- 5) Lab Task
- 6) Assignment # 01

Operators

- Operator is a symbol which is used to perform some operation.
- Operators are used to perform operations on variables and values.
- In the example below, we use the + operator to add together two values:
- \Rightarrow int x = 100 + 50;
- Although the + operator is often used to add together two values, like in the example above, it can also be used to add together a variable and a value, or a variable and another variable:

Example

```
int sum1 = 100 + 50; // 150 (100 + 50)
int sum2 = sum1 + 250; // 400 (150 + 250)
int sum3 = sum2 + sum2; // 800 (400 + 400)
```

- 1. Unary operators
- 2. Binary operators
- 3. Ternary operators

- 1. Increment (++)
- 2. Decrement (--)
- 3. Negation (!)

- 1. Arithmetic (+, -, *, /, %)
- 2. Relational (>, <, >=, <=, !=, ==)
- 3. Logical (&&, ||)
- 4. Assignment (=)
- 5. Arithmetic Assignment operator (+=, -=, *=, /=, %=)

3) Ternary Operator

Conditional operator (?:)

Example

```
(condition) ? statement 1 : statement 2;
int result= (n1>n2) ? n1 : n2;
```

3) Ternary Operator...

```
#include<iostream>
using namespace std;
                                                  Output: Good evening.
int main()
    int time = 20;
    string result = (time < 18) ? "Good day." : "Good evening.";</pre>
    cout << result;</pre>
    return 0;
```

Arithmetic Operators in C++

Arithmetic operators are used to perform common mathematical operations.

| Operator | Name | Description | Example |
|----------|----------------|----------------------------------|---------|
| + | Addition | Adds together two values | x + y |
| - | Subtraction | Subtracts one value from another | x - y |
| * | Multiplication | Multiplies two values | x * y |
| 1 | Division | Divides one value by another | x / y |
| % | Modulus | Returns the division remainder | x % y |

```
#include<iostream>
using namespace std;
int main()
    int n1, n2, sum;
    cout<<"Enter first number:\t";</pre>
    cin>>n1;
    cout<<"Enter 2nd number:\t";</pre>
    cin>>n2;
    sum=n1+n2;
    cout<<"The sum is:\t"<<sum<<endl;</pre>
```

```
Enter first number: 3
Enter 2nd number: 6
The sum is: 9
DS E:\EAST NUCES Dechawan\Muhammad
```

Assignment operators are used to assign values to variables.

In the example below, we use the **assignment** operator (=) to assign the value **10** to a variable called **x**:

Example

int
$$x = 10$$
;

Arithmetic Assignment Operator

The **addition assignment** operator (+=) adds a value to a variable:

```
Example int x = 10; x += 5;
```

Arithmetic Assignment Operator...

A list of all arithmetic assignment operators:

| Operator | Example | Same As |
|----------|---------|-----------|
| = | x = 5 | x = 5 |
| += | x += 3 | x = x + 3 |
| -= | x -= 3 | x = x - 3 |
| *= | x *= 3 | x = x * 3 |
| /= | x /= 3 | x = x / 3 |
| %= | x %= 3 | x = x % 3 |

Relational/Comparison Operators

- Comparison operators are used to compare two values.
- ❖ Note: The return value of a comparison is either true (1) or false (0).
- ❖ In the following example, we use the **greater than** operator (>) to find out if 5 is greater than 3:

Example

```
int x = 5;
int y = 3;
cout << (x > y); // returns 1 (true) because 5 is greater than 3
```

Relational/Comparison Operators

A list of all relational operators:

| Operator | Name | Example |
|----------|--------------------------|---------|
| == | Equal to | x == y |
| != | Not equal | x != y |
| > | Greater than | x > y |
| < | Less than | x < y |
| >= | Greater than or equal to | x >= y |
| <= | Less than or equal to | x <= y |

Logical Operators

Logical operators are used to determine the logic between variables or values:

| Operator | Name | Description | Example |
|----------|-------------|---|--------------------|
| && | Logical and | Returns true if both statements are true | x < 5 && x < 10 |
| II | Logical or | Returns true if one of the statements is true | x < 5 x < 4 |
| ! | Logical not | Reverse the result, returns false if the result is true | !(x < 5 && x < 10) |

- 1. Increment Operator (++)
- Decrement Operator (--)

1) Increment Operator

The operators that is used to add 1 to the value of a variable is called increment operator.

2) Decrement Operator

The operator that is used to subtract 1 from the value of a variable is called decrement operator.

- ❖ The increment operator is represented by a double plus (++) sign.
- ❖ It is used to add 1 to the value of an integer variable.
- This variable can be used before or after the variable name.
- For example, to add 1 to a value of variable xy, it is normally written as

$$xy = xy + 1;$$

❖ By using increment operator "++" it is written as

- *The increment operator can be written either before or after the variable.
- If it is written before the variable, it is known as **prefixing**.

If it is written after the variable, it is known as **post fixing**.

Prefix and postfix operators have different effects when they are used in expressions.

21

i) Prefix Increment Operator

*When an increment operator is used in prefix mode in an expression, it adds 1 to the value of the variable **before** the values of the variable is used in the expression.

i) Prefix Increment Operator...

```
#include<iostream>
using namespace std;
int main()
    int a=2;
    int b=3;
    int c=2;
    int result=a+b+(++c);
    cout<<"Result is: "<<result;</pre>
    cout<<"\nValue of c is: "<<c;</pre>
```

```
Result is: 8
Value of c is: 3
```

- In the above program, 1 will be added to the value of **c** before it is used in the expression.
- ❖Thus after execution, the result will be equal to 8 and the value of c will be 3.

- *When an increment operator is used in postfix mode in an expression, it adds 1 to the value of the variable after the value of the variable is used in the expression.
- **For Example,** if in the above example, increment operator is used in postfix mode, the result will be different. The statement will be shown below:

result =
$$a + b + c++$$
;

ii) Postfix Increment Operator...

In this case, 1 will be added to the value of c after its existing value has been used in the expression. Thus after execution, the result will be equal to 7 and the value of c will be 3.

ii) Postfix Increment Operator...

```
#include<iostream>
using namespace std;
int main()
    int a=2;
    int b=3;
    int c=2;
    int result=a+b+(c++);
    cout<<"Result is: "<<result;</pre>
    cout<<"\nValue of c is: "<<c;</pre>
```

Result is: 7
Value of c is: 3

- ❖ The decrement operator is represented by a double minus (--) sign.
- ❖ It is used to subtract 1 from the value of an integer variable.
- This variable can be used before or after the variable name.
- ❖ For example, to subtract 1 from the value of variable xy, the decrement statement is written as

i) Prefix Decrement Operator

*When decrement operator is used in prefix mode in an expression, it subtracts 1 from the value of the variable **before** the values of the variable is used in the expression.

i) Prefix Decrement Operator...

```
#include<iostream>
using namespace std;
int main()
    int a=2;
    int b=3;
    int c=2;
    int result=a+b+(--c);
    cout<<"Result is: "<<result;</pre>
    cout<<"\nValue of c is: "<<c;</pre>
```

```
Result is: 6
Value of c is: 1
```

i)Prefix Decrement Operator...

- In the above program, 1 will be subtracted from the value of **c** before it is used in the expression.
- Thus after execution, the result will be equal to 6 and the value of **c** will be 1.

- *When an decrement operator is used in postfix mode in an expression, it subtracts 1 from the value of the variable after the values of the variable is used in the expression.
- ❖ For Example, if in the above example, decrement operator is used in postfix mode, the result will be different. The statement will be shown below:

result =
$$a + b + c$$
--;

ii) Postfix Decrement Operator...

In this case, 1 will be subtracted from the value of **c** after its existing value has been used in the expression. Thus after execution, the result will be equal to 7 and the value of c will be 1.

ii) Postfix Decrement Operator...

```
#include<iostream>
using namespace std;
int main()
    int a=2;
    int b=3;
    int c=2;
    int result=a+b+(c--);
    cout<<"Result is: "<<result;</pre>
    cout<<"\nValue of c is: "<<c;</pre>
```

```
Result is: 7
Value of c is: 1
```

Ask user to enter a three digit number and then display the number in reverse order.

- Write a C++ program that will convert dollar to rupees (Dollar to Rupees Conversion Calculator).
- Write a C++ program that will convert rupees to dollar (Rupees to Dollar Conversion Calculator).
- 3) Write a C++ program that will convert centigrade to Fahrenheit.
- 4) Take student name and marks of your 2nd semester from user and then generate DMC which will contain obtained marks out of total and percentage.
